- 1 Introduction
- 2 Merging mechanistic and ML models
  - Concepts
  - Mechanistic models augmented with ML
  - Knowledge informed ML
- 3 Research Directions
- 4 References

## Machine learning

- Can find patterns in problems where complexity prohibits the explicit programming of a system's exact physical nature.
- Not enough data to train sufficiently generalized models.
- Purely data-driven model might not meet constraints such as dictated by natural laws
- Need for models to be interpretable and explainable
- Require homogeneous labeled training data

## Mechanistic models

- “A picture is worth a thousand words” -i “A model is worth a thousand datasets” [7]
- Often, cannot capture complex dynamics in the system
- They are simplified to allow for handling complexity

## Hybrid models

- Best of both worlds
- Can be complex and difficult to train

- *General knowledge*: knowledge independent of the task and data domain.
- *Domain knowledge*: knowledge in any field such as biology, physics, chemistry, and engineering.

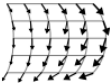

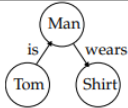

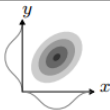

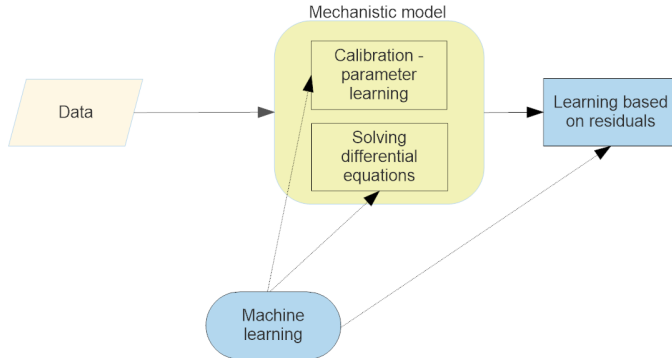

Algebraic Equations	Logic Rules	Simulation Results	Differential Equations	Knowledge Graphs	Probabilistic Relations
$E = m \cdot c^2$ $v \leq c$	$A \wedge B \Rightarrow C$		$\frac{\partial u}{\partial t} = \alpha \frac{\partial^2 u}{\partial x^2}$ $F(x) = m \frac{d^2 x}{dt^2}$		

Figure: Domain knowledge representation [11]<sup>1</sup>

<sup>1</sup>Note that many figures are copied and the sources are referenced!

*Informed machine learning* describes learning from a hybrid information source that consists of data and prior knowledge. The prior knowledge is pre-existent and separated from the data and is explicitly integrated into the machine learning pipeline [11].

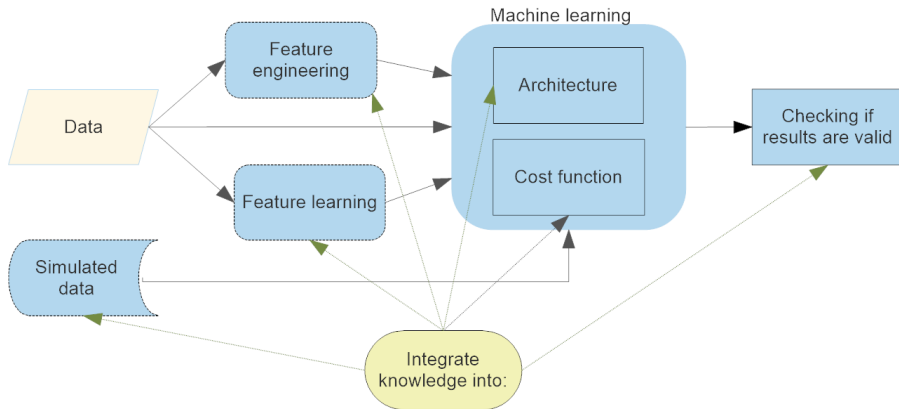

Figure: Machine learning flow [11]

- The hypothesis: the obtained solution from the first principles model does not explain the system behavior -  $\hat{y}$  created features are still well-correlated with the target variable (mismatch).
- ML aims to learn the residual pattern of the system behavior.

- $y_{ML}$ : machine learning predicted label
- $y_{DK}$ : domain knowledge predicted label
- $y_{true}$ : ground truth label

Figure: Residual modeling [4]

- The ML model serves as an estimator of unmeasured process parameters that are difficult to model from first principles
- Used to model a fedbatch bioreactor [6]

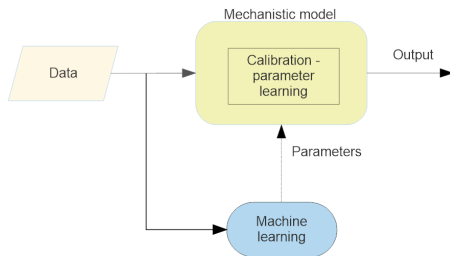

Figure: Parameter estimation

- Data: Biomass concentration at time  $k$
- Output: Predicted biomass concentration at  $k + 1$
- Unobserved parameter: Growth rate

Infer solutions to partial differential equations, and obtain physics-informed surrogate models [9]:

- Neural networks can represent an arbitrary functions when given appropriate weights.
- Therefore it can approximate any arbitrary function that represents a solution of a differential equation:  $u = NN(x)$
- We can also find  $du/dx$ ,  $d^2u/dx^2$  through back-propagation.
- Assume that we are given a differential equation with boundary conditions.
- The goal is to minimize the mean square error loss formed by differential equation and boundary conditions using automated differentiation.

## Training data

- Features
  - feature engineering
- Data augmentation
  - image transforms
  - simulations:  
generate a large amount of data from mechanistic models for training.

## Feature learning

- Unsupervised learning - knowledge can still be incorporated
- Variational autoencoders
  - VAEs jointly learn an inference model and a generative model, allowing them to infer latent variables from observed data.

Figure: Understanding Variational Autoencoders

- $Mass = Density \cdot Volume$ : ML does not know that this is not supposed to be violated
- Domain knowledge is into a loss function and performs regularization

- function  $L()$  is machine learning loss function
- function  $G()$  is regularization term: a measure of consistency between domain knowledge and predicted label
- function  $M_{DK}()$ : a domain knowledge transformation of feature  $X$

Figure: Knowledge in the loss function [4]

- Model structure incorporates the mechanistic model
- We will introduce state-space models first and show how they can be integrated with RNNs
- Integration is done with variational autoencoders

## State-space models:

- probabilistic scenarios: We do not have perfect knowledge about the state of the system, and the system can develop non-deterministically over time
- are numerically efficient to solve
- can describe differential equations

- Transition equation:

$$\mathbf{z}_t = \mathbf{A}_t \mathbf{z}_{t-1} + \mathbf{B}_t \mathbf{u}_t + \epsilon_t$$

- Emission equation:

$$\mathbf{x}_t = \mathbf{C}_t \mathbf{z}_t + \delta_t$$

Figure: Linear state-space model [3]

## Kalman filter:

- Kalman filter is optimal for linear Gaussian problems.
- Generalizes many common time-series models
- Strong modelling assumptions:
  - Linear transitions and emissions
  - Gaussian transitions and measurement noise

## Non-linear filters

- Extended Kalman filters (non-linear observation equation, Gaussian noise)
- Particle filters (non-linear, non Gaussian)
- Problems
  - Transition model still have difficulties handling complex non-linear dynamics
  - Does not capture long-term dependencies in data (Markov models)

## SRNN

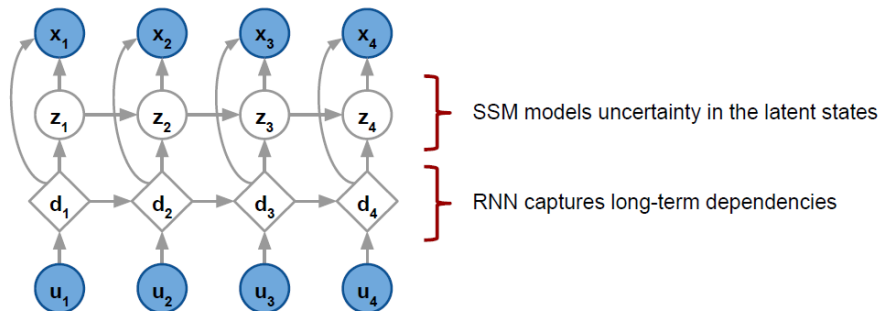

Figure: Merged RNN and state-space model [3]

- Each data points is a random variable generated from multivariate normal distribution
- The relationship between random variables determines the shape of the latent function.
- Advantages:
  - Regression and prediction with confidence intervals [10]
  - Learning the parameters of the state space models or differential equations [8]
  - Time series where data is not uniformly sampled.
  - Allow for Bayesian optimization

Figure: Gaussian process regression example [8]

Incorporating human knowledge into:

- Reward
- Policy and action selection
- Building the overall **controller**

Figure: Probabilistic model of decision-making problem of an agent. The oval nodes represent the state ( $S$ ) and the observation ( $O$ ). The rectangle is the decision node ( $A$ ) and the diamond is the reward function ( $R$ ). [2]

- Design a simulator that will allow us to simulate the bioprocess and bioreactor based on mechanistic or hybrid model [5]. This is important for:
  - digital twin
  - generating data for testing algorithms
- Merging mechanistic and ML models in this field has just started
  - there is great research opportunity to be first to apply some of these ML approaches on data from bioreactor.
- Gaussian processes for uncertainties and optimization

- Pre-training or intelligent initialization of the parameters of the ML model
  - Transfer learning

Figure: Transfer learning [1]

- Meta learning
  - learning from other processes
  - from our data collected using different sensors and in different ways

GPU Support	CUDA	CUDA	OpenCL	CUDANative.jl + CuArrays.jl	Built-in	Built-in
Distributed Dense Linear Algebra	ScaLAPACK	Elemental	None	Elemental.jl	Built-in	torch.distributed (no factorizations)
Scale	None	Poor	Fair	Excellent		
Explanation	No automatic differentiation compatible library exists. Suggestion for a library to wrap.	Functionality exists, but is feature-incomplete or AD compatibility is incomplete. If no AD support, then AD support can easily be added since the library already defines adjoints.	The basic features exist, but has some major features missing or are not AD-compatible.	Has all of the main features and is fully compatible with the automatic differentiation tooling.		

Figure: Comparison of tools readily usable with differentiable programming (automatic differentiation) frameworks copied from [here](#)
